(57) **ABSTRACT**

A support for portable electronic devices increases passenger convenience and comfort. The support may comprise an elongated cavity or slot configured to accept one or more portable electronic devices. The slot is collapsible to help secure a portable electronic device therein or for storage purposes. The portable electronic devices may be held at various viewing angles relative to the passenger. A passenger may be permitted to adjust the angle at which his or her portable electronic device is positioned. Likewise, an operator or the like may rotate the support for cleaning or other maintenance.

ELECTRONIC DEVICE SUPPORT FOR VEHICLES

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation-in-part of U.S. patent application Ser. No. 14/203,547, filed Mar. 10, 2014, which is a continuation-in-part of U.S. patent application Ser. No. 13/644,382, filed Oct. 4, 2012, now U.S. Pat. No. 8,667,904, which claims priority of U.S. Provisional Patent Application No. 61/641,098, filed May 1, 2012 and to U.S. Provisional Patent Application No. 61/546,969 filed Oct. 13, 2011.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The invention relates to vehicular entertainment, and in particular to an electronic device support for vehicles.

2. Related Art

Airplane tray tables have been largely unchanged for decades. In general, such tray tables move between a stowed upright position and a service position where a tray table is generally horizontal so that items may be supported by the tray table. In the service position, the tray table may be used to support food, drink, and other items for a passenger. Though positioned directly in reach of a passenger, traditional tray tables are limited to such functionality.

From the discussion that follows, it will become apparent that the present invention addresses the deficiencies associated with the prior art while providing numerous additional advantages and benefits not contemplated or possible with prior art constructions.

SUMMARY OF THE INVENTION

A support for portable electronic devices is disclosed herein. As will be detailed herein, the support allows passengers to easily secure portable electronic devices within a vehicle at various viewing or use positions. In this manner, entertainment or other services may be enjoyed while preserving passenger comfort. In addition, the support is highly versatile in that it is configured to accept various electronic devices and even multiple electronic devices at once, while also being easily stowed. In some embodiments, the support may be rotatable to allow passengers of different heights and having different preferences to position portable electronic devices as they desire, and to allow for cleaning and maintenance of the support.

Various embodiments and methods related to the support are disclosed herein. For instance, in one exemplary embodiment, a support may comprise a tray table for holding a portable electronic device in a vehicle, with such tray table may comprising a body having a top surface for supporting one or more items, a slot in the body comprising a first wall, and a second wall. The second wall is formed by a presser. The slot is dimensioned to receive an edge of a planar portable electronic device and to hold the planar portable electronic device upright when the planar portable electronic device is received within the slot. A biasing device is connected to the presser that forces the presser towards the first wall. One or more mounts for attaching the tray table to a portion of the vehicle are included as well.

The presser may have an angled distal end, or be round to allow the slot to receive a portable electronic device without obstruction. A pivot may be at a bottom of the slot to secure the presser in a rotatable fashion. An opening may be at a

bottom of the slot. In addition, the first wall may be taller than the second wall, or vice versa.

A rotatable assembly may be included as well. The rotatable assembly may comprise a recess in the body, a rotatable body, wherein the slot is formed in the rotatable body, and one or more rotatable mounts securing the rotatable body to the body within the recess.

In another exemplary embodiment, a support may be a tray table comprising a body having a top surface and a back end, one or more mounts for attaching the tray table to a portion of the vehicle, and a bracket comprising a base and an upright at a back end of the tray table. One or more slides at the body slidably secure the bracket to the body, such that the bracket is movable between a retracted position and an extended position. A collapsible slot comprising a bottom formed by the base of the bracket, a front wall formed by the back end of the body, and a back wall formed by the upright of the bracket is also included. The collapsible slot is collapsed when the bracket is in the retracted position and is expanded when the bracket is in the extended position. Also, the collapsible slot is dimensioned to receive an edge of the portable electronic device and hold the portable electronic device upright when expanded.

A biasing device may be connected to the bracket that pulls the bracket towards the body. An opening may be in the bottom of the collapsible slot for cleaning and maintenance purposes. The slides may each comprise one or more pegs and a rail. The upright of the bracket may be formed by a pivoting presser. Also, a biasing device that forces the pivoting presser towards the front wall may be provided. The base and the upright of the bracket may be at a non-perpendicular angle relative to one another.

A method for holding a portable electronic device in a vehicle may comprise providing a tray table having a body comprising a slot having a first wall and a second wall, moving the second wall away from the first wall, receiving an edge of the portable electronic device in the slot, holding the portable electronic device upright relative to a top surface of the tray table with the slot, and attaching a portion of the tray table to the vehicle to secure the tray table thereto.

A biasing device may be attached to the second wall that forces the second wall towards the first wall. The second wall may be formed with a slidable bracket that is movable inward and outward at a back end of the body. In addition, an opening may be formed in a bottom of the slot. A rotatable body may be provided within a recess of the body. In such case, the slot will be formed in the rotatable body. The method may also include forming a rounded or angled distal end of the second wall.

Other systems, methods, features and advantages of the invention will be or will become apparent to one with skill in the art upon examination of the following figures and detailed description. It is intended that all such additional systems, methods, features and advantages be included within this description, be within the scope of the invention, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

The components in the figures are not necessarily to scale, emphasis instead being placed upon illustrating the principles of the invention. In the figures, like reference numerals designate corresponding parts throughout the different views.

FIG. 4D is a cross sectional view of an exemplary tray table with rotatable support in operation;

FIG. 4E is a top view of an exemplary tray table with rotatable support in operation;

FIG. 4F is a back perspective view of an exemplary tray table with rotatable support in a closed position;

FIG. 4G is a back perspective view of an exemplary tray table with rotatable support in an intermediate position;

FIG. 4H is a back perspective view of an exemplary tray table with rotatable support in an open position;

FIG. 4I is a front perspective view of an exemplary tray table with rotatable support in an open position;

FIG. 4J is a side cross sectional view of an exemplary tray table with rotatable support in operation;

FIG. 4K is a side cross sectional view of an exemplary tray table with rotatable support in operation;

FIG. 4L is a back cross sectional view of an exemplary tray table with rotatable support in operation;

FIG. 5A is a top perspective view of an exemplary tray table with support having separable portions;

FIG. 5B is a top perspective view of an exemplary tray table with support having separable portions;

FIG. 5C is a top view of an exemplary tray table with support having separable portions in use;

FIG. 6A is a cross sectional view of an exemplary tray table with support having a biasing mechanism;

FIG. 6B is a cross sectional view of an exemplary tray table with support having a biasing mechanism;

FIG. 6C is a cross sectional view of an exemplary tray table with support having a biasing mechanism;

FIG. 6D is a cross sectional view of an exemplary tray table with support having a biasing mechanism;

FIG. 6E is a cross sectional view of an exemplary tray table with rotatable support having a biasing mechanism;

FIG. 6F is a cross sectional view of an exemplary tray table with rotatable support having a biasing mechanism;

FIG. 6G is a perspective view of an exemplary tray table with rotatable support having a biasing mechanism;

FIG. 6H is a top perspective view of an exemplary rotatable support having a biasing mechanism;

FIG. 6I is a bottom perspective view of an exemplary rotatable support having a biasing mechanism;

FIG. 6J is a top perspective view of an exemplary rotatable support having a biasing mechanism;

4

FIG. 6K is a bottom perspective view of an exemplary rotatable support having a biasing mechanism;

FIG. 7A is a cross sectional view of an exemplary tray table with support having a collapsible slot;

FIG. 7B is a cross sectional view of an exemplary tray table with support having a collapsible slot;

FIG. 7C is a bottom view of an exemplary tray table with support having a collapsible slot; and

FIG. 7D is a bottom view of an exemplary tray table with support having a collapsible slot.

DETAILED DESCRIPTION OF THE INVENTION

In the following description, numerous specific details are set forth in order to provide a more thorough description of the present invention. It will be apparent, however, to one skilled in the art, that the present invention may be practiced without these specific details. In other instances, well-known features have not been described in detail so as not to obscure the invention.

In general, the tray table herein provides is a versatile support for one or more portable electronic devices. As will be described further below, the tray table may be configured to hold portable electronic devices of various shapes and sizes. This is advantageous in that it allows passengers to enjoy use of their personal electronic devices during a flight air or other vehicular travel. For example, passengers may access and enjoy various media or other entertainment via their electronic devices during a flight, road trip, cruise, or bus or train ride. Using the tray table, passengers avoid having to hold, prop up, or otherwise secure their electronic devices in unorthodox ways, such as by leaning the devices against various surfaces at their seats. In addition, the tray table increases passenger comfort by holding portable electronic devices in an ergonomic position. In some embodiments, as will be described further below, the tray table's support may be rotatable or movable to allow adjustments to the position of a portable electronic device.

FIG. 1A provides a top perspective view of an exemplary tray table **104** having a support **108** for portable electronic devices. As can be seen, the tray table **104** provides a planar top surface **112** that passengers may place their various items on. The tray table **104** may also include one or more mounting points **116** or mounts that allow it to be installed in an aircraft, such as on a back portion an aircraft passenger seat. In typical embodiments, the tray table **104** will mount to the rotatable tray table support arms of aircraft passenger seats. Mounting points may be at or near a back end **120** of the tray table **104**. The mounting points **116** will typically allow the tray table **104** to rotate or otherwise move so as to allow the tray table to be moved between a stowed position (where it is secured to a seat back) and a service position (where it is substantially horizontal to support items on its top surface).

As can also be seen, the support **108** may be positioned at the back end **120** of the tray table **104**. This allows the portion of the top surface **112** in front of the support **108** to be used even when the support **108** is in use. It is contemplated that the support **108** may be located at different locations as well. For instance, the support **108** may be near a front end **124** of the tray table **104**, at a central portion **128**, or elsewhere. Typically, the support **108** will extend laterally across the tray table **104** parallel to the back edge of the tray table, however it is contemplated that the support **108** may be angled slightly in some embodiments.

In one or more embodiments, the support **108** may be an excavated portion of the tray table **104** configured to accept a portable electronic device. For instance, the support **108** may

5

be a cavity **132** formed in the body **136** of the tray table **104** for instance. For example the cavity **132** may be a slot or groove. The cavity **132** may comprise a front wall **140** and a back wall **144**, and one or more sidewalls **148**.

It is noted that the tray table **104** may include one or more magnets **164** at or near its top surface **112** to hold a portable electronic device on the top surface. In operation, the magnets **164** would be attracted to a magnetic structure within the portable electronic device, thus holding the portable electronic device. Though shown at particular locations in FIG. **1A**, it is contemplated that the magnets **164** may be at various locations of the tray table **104**. In addition, fewer or additional magnets **164** may be provided in one or more embodiments.

FIGS. **1B-1C** provide cross sectional views of the tray table **104** and support **108**. FIG. **1B** is a cross sectional view across Line **1**, while FIG. **1C** is a cross sectional view across Line **2**. As can be seen, the cavity **132** may have a bottom **152** to provide support to a portable electronic device thus preventing the device from sliding out of the support **108** through its bottom. It is noted that the bottom **152** may have one or more openings **156** to allow ventilation and to allow any spilled liquids or other debris to fall out of the support **108**. This aids in keeping the support clean.

It is contemplated that the support **108** may be configured to provide connectivity to any device it is holding. For instance, in one embodiment, the support **108** may optionally include an electrical, optical, or other connectors **168** to provide power or data connections to a portable electronic device. If a connector **168** is provided, it is contemplated that one or more magnets may optionally be used to secure a connector **168** to a portable electronic device. In some embodiments, the support **108** may provide wireless connectivity to power or data connections. For example, the support **108** may provide inductive battery charging or a short-range data connection (such as a Bluetooth™ connection) to portable electronic devices. The tray table **104** may contain its own power source, such as one or more batteries, and/or may be connected to an aircraft's power system. The batteries may be rechargeable. In one or more embodiments, the batteries may be held in a compartment within the tray table **104** and be removable therefrom, such as for replacement, recharging, or both.

FIG. **1D** illustrates a cross sectional view of an additional embodiment of the support **108**. As can be seen, the cavity **132** may be "L" shaped thus providing a bottom **152** to support a portable electronic device. The lower portion of the "L" shape terminates at an opening near the back end of the tray table **104**. This is advantageous in that it causes any fluids (or other dirt/debris) to flow toward the back of the tray table. In the event of a spill, such fluids would exit the tray table **104** away from the passenger as much as possible. It is noted that rather than forming the entire cavity **132** into an "L" shape, one or more channels/openings, could form the bottom of the "L" shape and guide fluids (or other dirt/and debris) toward the back of the tray table.

It is contemplated that a removable liner may be provided in some embodiments to aid in keeping the support clean. The liner may conform to the cavity **132** and may be removed and replaced with a new liner when dirty. Alternatively or in addition, a plug, cap or other covering may be provided to fill the cavity **132** to prevent dirt or debris from entering the support **108**. Typically, the plug or cover would have a planar top positioned flush with the top surface **112** of the tray table **104**, when inserted into the cavity **132**. It is contemplated that the plug or cover may be affixed to the cavity **132** in some embodiments. For instance, the plug or cover may be a spring loaded or other biased mechanism that may be depressed

6

downward to provide access to the cavity **132**, thereby allowing an electronic device **204** to be inserted into the support **108**. When not depressed, the biasing mechanism would raise the plug or cover such that it is flush with the top surface **112** of the tray table.

Referring to FIG. **1B**, the support **108** may be angled in one or more embodiments. For instance, the support **108** may have a back wall **144** and/or front wall **140** that is at a non-perpendicular angle to the top surface **112** or body **136** of the tray table. As will be described further below, this allows the support **108** to hold a portable electronic device at an angle, which causes the device to face a seated passenger for ideal viewing. In one or more embodiments, the support **108** will be angled rearward towards the back end or edge of the tray table **104** to accomplish this.

It is contemplated that the cavity **132** may have various other cross sectional shapes as well. For example, the front wall **140** and back wall **144** may form a "V" or other shape that tapers from the top surface **112** of the tray table **104**. This allows portable electronic devices of various thickness thicknesses to be inserted into and securely held by the cavity **132**. Alternatively or in addition, the cavity **132** may have a stepped cross section to produce a set of discrete widths between the front wall **140** and back wall **144**. In other words, the front wall **140** and/or back wall **144** may be shaped like steps. This also allows portable electronic devices of various thicknesses to be supported by the cavity **132**.

FIG. **1E** is a bottom view of the tray table **104** showing the opening **156**, which allows dirt and debris to exit the support **108**. As can be seen, the opening **156** extends to the bottom surface **160** of the tray table **104** so that dirt and debris can fall out of the tray table **104**. The opening **156** will typically be smaller than the cavity **132** so that an electronic device may be supported therein without falling through the opening. For example, the opening **156** may have a smaller width and/or length than the support **108**. Though shown as a single opening **156** in FIG. **1E**, it is contemplated that a plurality of openings may be used.

In addition, an opening **156** may be formed in various shapes and sizes. For example, an opening may have a length of 1-2 inches in some embodiments. This is advantageous in that such opening **156** is large enough to allow dirt and debris to escape while not being so large as to result in a smaller electronic device (such as a phone or other handheld device) to fall through the opening. In one or more embodiments, the bottom **152** of the support **108** may slant towards the opening **156** so as to guide dirt and debris toward the opening.

In one or more embodiments, the body **136** may be constructed to aid in cleaning the tray table **104**. For example, the body **136** or portions thereof may be formed from material having anti-microbial or anti-bacterial qualities. In some embodiments, the body **136** or portions thereof may be coated with such materials. It is noted that only portions of the tray table **104**, such as the top surface **112** may be formed from or coated with anti-microbial and/or anti-bacterial materials.

It is contemplated that a removable liner may be provided in some embodiments to aid in keeping the support clean. The liner may conform to the cavity **132** and may be removed and replaced with a new liner when dirty. Alternatively or in addition, a cover **172**, cap or other covering may be provided to fill the cavity **132** to prevent dirt or debris from entering the support **108**. Typically, the cover **172** would have a planar top positioned flush with the top surface **112** of the tray table **104**, when inserted into the cavity **132**, such as shown in FIG. **1F**. FIG. **1F** is a top view of an exemplary tray table **104** having a support **108**. It is contemplated that the cover **172** may be affixed to the cavity **132** in some embodi-

7

ments. For instance, the cover **172** may be a spring loaded or other biased mechanism that may be depressed downward to provide access to the cavity **132**, thereby allowing an electronic device **204** to be inserted into the support **108**. When not depressed, the biasing mechanism would raise the cover **172** such that it is flush with the top surface **112** of the tray table.

FIG. 2 illustrates an exemplary tray table **104** having a portable electronic device **204** installed therein. As can be seen, the portable electronic device **204** may be held by the support **108** at a reclined angle, such as described above. It is contemplated that the support **108** may have a length selected to accommodate a variety of portable electronic devices. For instance, as can be seen from FIG. 2, the support **108** may accept a tablet device but also is sized to allow smaller devices, such as portable media players, smart phones, and portable gaming machines, to be held.

It is contemplated that the support **108** may be configured to provide connectivity to any device it is holding. For instance, the support **108** may have electrical, optical, or other terminals to provide power or data connections to a portable electronic device. In some embodiments, the support **108** may provide wireless connectivity to power or data connections. For example, the support **108** may provide inductive battery charging or a short-range data connection (such as a Bluetooth™ connection) to portable electronic devices. The tray table **104** may contain its own power source, such as one or more batteries, and/or may be connected to an aircraft's power system. The batteries may be rechargeable. In one or more embodiments, the batteries may be held in a compartment within the tray table **104** and be removable therefrom, such as for replacement, recharging, or both.

As disclosed above, the tray table may provide an adjustable support in some embodiments, such as to permit passengers to position their portable electronic devices at various angles. As will now be described with regard to FIGS. 3A-3C, the tray table **104** may include a rotatable assembly to allow such positioning.

FIG. 3A provides a top perspective view of the tray table **104**. As can be seen, the outward appearance of an adjustable embodiment, may be similar to that disclosed above. In one or more embodiments, a control device **304** may be provided to allow the position of the support **108** to be changed. As shown, an adjustment wheel is provided as the control device **304**. It is noted that various control devices, such as knobs, levers, sliders, buttons, or the like may be used to move the support **108**. In addition, multiple control devices **304** may be provided. For instance an adjustment wheel or other control device **304** could be on both sides of the support **108** in some embodiments.

It is also noted that the support **108** may be biased (such as by one or more springs) in some embodiments. In this manner, the support **108** may be configured to automatically move or rotate to a particular position when a control device **304** is engaged, as will be described further below.

FIG. 3B provides a cross sectional view of the tray table across Line 1 of FIG. 3A. As can be seen the body **136** of the tray table **104** may be configured to accommodate a rotatable assembly **308**. For example, as shown in the embodiment of FIG. 3B, a compartment **312** comprising a curved front and back wall **316**, **320** configured to accept the rotatable assembly **308** while allowing the rotatable assembly to rotate or move within the compartment is provided. The compartment **312** may include a bottom **324** to enclose the rotatable assembly **308**. An optional bottom **324** may be provided in some embodiments. It is noted that without a bottom **324**, any dirt or debris that collects in the rotatable assembly **308** can be

8

removed by rotating the assembly such that such debris can fall out of the assembly. Alternatively, an opening **156** may be formed in the bottom **324** of the compartment **312** to allow such dirt and debris to exit the assembly **308**.

It is contemplated that the compartment **312** may extend from the top surface to the bottom surface of the tray table's body **136** in some embodiments. In this manner, the compartment **312** would have an opening at its top and bottom. This allows electronic devices to be received in the cavity **132** via the top opening of the compartment **312** while also allowing dirt and debris to exit the assembly via the bottom opening of the compartment. The body **332** of the rotatable assembly **308** may be sized to protrude from both the top and bottom opening of the compartment **312**. In this manner, the body **332** itself forms a seal with the compartment **312** thereby preventing dirt and debris from entering the assembly **308**.

The rotatable assembly **308** may comprise a body **332** having a cavity **132** therein to accept a portable electronic device. Similar to above, the cavity **132** may comprise a front wall **140**, a back wall **144**, and one or more sidewalls **148**. A bottom **152** may be provided to prevent a portable electronic device from falling out of the cavity **132**, such as described above. As can be seen, the cavity **132** may be angled to hold a portable electronic device at an angled position, such as described above. It is contemplated that the cavity **132** may be not be angled (i.e., be perpendicular to the axis of rotation) in some embodiments. With the rotatable assembly **308** for instance, a passenger may choose his or her desired angle by rotating the rotatable assembly. Thus, the cavity **132** itself may but need not be angled in all embodiments.

The body **332** or portion thereof of the rotatable assembly **308** may be rounded or cylindrical in one or more embodiments, such as to allow the rotatable assembly to rotate within the tray table **104**. It is contemplated that the body **332** or portion thereof could have other cross sectional shapes. For example, the body **332** may be triangular, a pentagon, hexagon, or other shape. In some embodiments, the shape of the body **332** may be used to help hold the body **332** in position after it has been rotated. For example, the shape of the body may cause it to engage other surfaces of the tray table **104** thus holding the body in position.

One or more holding mechanisms may be used to hold the rotatable assembly **308** in a particular position. For example, a biased braking pad or other surface may press against the rotatable assembly **308** (such as at the body **332**) to prevent the rotatable assembly from rotating out of a desired position. Other holding mechanisms, such as removable locking pins, detents, or the like could be used as well. In addition, it is contemplated that the body **332** may closely conform to its compartment **312** to hold itself in position once rotated to a desired position.

FIG. 3C illustrates a cross sectional view of the tray table **104** across Line 2 of FIG. 3A. As can be seen, the rotatable assembly **308** may comprise one or more axels **336** upon which its rotation may be accomplished. The axels **336** may extend to engage a portion of the rotatable assembly's compartment **312** to support the rotatable assembly **308** therein.

As shown in FIG. 3C, an axel **336** may also be mechanically linked to a control device **304** in one or more embodiments. In this manner, the axel **336** and thus the rotatable assembly **308** may be rotated by manipulating a control device **304**. For example, in FIG. 3C rotating the control device **304** also rotates the rotatable assembly **308**. It is noted that one or more biasing devices, such as springs, may engage or be attached to an axel **336** as well. This allows the rotatable assembly **308** to automatically move to a particular position when a biasing device is activated. For example, a biasing

device may be configured to rotate the cavity 132 of the rotatable assembly 308 such that it is accessible from the top of the tray table 104. Alternatively, a biasing device could rotate the cavity 132 such that it is inaccessible, thus "closing" the support 108. This may be desirable to prevent unwanted dirt or debris from entering the cavity 132, such as during food service on a flight.

FIGS. 4A-4B illustrate a rotatable assembly 308 in operation. As can be seen, the rotatable assembly 308 may rotate from the open position shown in FIG. 4A to the closed position shown in FIG. 4B. In the open position, the cavity 132 of the rotatable assembly 308 is typically accessible, thus allowing one or more portable electronic devices 204 to be supported therein, such as shown in FIG. 4A.

When not in use, the rotatable assembly 308 may be rotated to a closed position, such as shown in FIG. 4B. As can be seen, the cavity 132 may not be accessible when in the closed position. As stated, this prevents dirt or debris from entering the cavity 132. In embodiments where the tray table's compartment 312 has an open bottom, the rotatable assembly 308 may be rotated to empty any dirt or debris that may have collected therein. It is noted that the compartment 312 may have a removable bottom to allow this cleaning process to occur.

It is noted that the cavity 132 of the tray table 104 may be configured to protect any portable electronic devices it holds. For example, in one or more embodiments, the cavity 132 or portions thereof may be padded or be coated with non-abrasive surfaces to prevent the cavity from scratching or otherwise damaging the enclosure of a portable electronic device.

FIGS. 4C-4E illustrate another rotatable assembly 308 in operation. As can be seen, an elongated tab 404 extends from the body 332 of the rotatable assembly. The elongated tab 404 may be an elongated member, planar structure, or the like which extends from the body 332. In operation, a bottom portion of an electronic device may be placed in the support 108 while an upper portion is propped up against (i.e., held by) the tab 404. This can be seen from FIG. 4C, which illustrates the rotatable assembly 308 in an open position.

FIGS. 4D-4E illustrate the rotatable assembly 308 in a closed position. In one or more embodiments, the body 136 of the tray table 104 may have a recess 408 formed therein to accept the tab 404. In this manner, when closed, the rotatable assembly's tab 404 is positioned flush with the top surface 112 of the tray table 104. This prevents the rotatable assembly 308 from obstructing use of the tray table and provides a planar surface for placement of one or more items. In addition, as can be seen from FIGS. 4D-4E, the tab 404 also encloses the compartment 312 preventing dirt and debris from entering. A cutout or recess 412 may be provided to allow the tab 404 to be lifted in some embodiments.

Though shown in a compartment 312 having a bottom 324, it is noted that a bottom need not be provided in all embodiments having a rotatable assembly 308. For instance, as described above, the compartment 312 may have an open bottom to allow dirt and debris to exit the compartment. Alternatively, one or more openings may be formed in the bottom 324, such as described above with regard to FIG. 3B, to allow dirt and debris to exit the compartment 312.

FIGS. 4F-4I illustrate another exemplary tray table 104 having a rotatable assembly 308. FIGS. 4F-4G provide a back perspective view of the tray table 104. FIGS. 4H-4I respectively provide a back and front perspective view of the tray table 104. As can be seen, the rotatable assembly 308 may be formed at the back end 120 of the tray table 104 rather than inset from the back end as described with regard to the above embodiment. The rotatable assembly 308 may comprise a

body 332 having a cavity 132 for receiving and securing a portable electronic device 204.

The body 332 may be an elongated structure having flat sides. For instance, as shown in FIGS. 4F-4I, the body 332 is a rectangular shape extending laterally between a left and right side of the tray table 104 at the back end 120 of the tray table. In one or more embodiments, a lip 420 may extend from a portion of the body 332. As can be seen from FIG. 4F, the lip 420 may extend from a top portion of the body 332 so that it forms a barrier to prevent items on placed on the top surface 112 of the tray table 104 from sliding off the back end 120 of the tray table.

The cavity 132 will typically extend along the length of the body 332, such as shown. In one or more embodiments, the cavity 132 may be an elongated opening configured to accept a portion of one or more portable electronic device 204. As shown in FIGS. 4H-4I for example, the cavity 132 comprises a rectangular opening sized to accept an edge or end of a portable electronic device 204. This secures the portable electronic device 204 within the body 332 and allows a user to use the portable electronic device 204 without having to hold the portable electronic device.

Positioning the body 332 of the rotatable assembly 308 at the back end 120 of the tray table is advantageous in that it allows the cavity 132 to be exposed at the back end of the tray table. When the tray table 104 is in a stowed position, it will typically be in a vertical orientation with the front end 124 of the tray table being above the back end 120 of the tray table. In this manner, any dirt or debris in the cavity 132 would automatically fall out of the cavity keeping the cavity clean and unobstructed. Maintenance or other personnel may then collect such dirt and debris from the floor of the aircraft.

One or more openings 156 may be at the bottom of the cavity 132 in one or more embodiments to also aid in keeping the cavity clean. Typically, an opening 156 will extend from the bottom of the cavity 132 to an external surface of the body 332. This allows any dirt or debris that enters the cavity 132 to fall out of the cavity keeping the cavity clean. FIG. 4G illustrates an exemplary opening 156.

FIGS. 4F-4I also illustrate operation of the tray table 104 as its rotatable assembly 308 rotates from a closed position, as shown in FIG. 4F, to an open position as shown in FIGS. 4H-4I. FIG. 4G illustrates the rotatable assembly 308 in an intermediate position as it rotates between an open and closed position.

In the closed position, the body 332 of the rotatable assembly 308 forms a portion of the top surface 112 of the tray table 104. For instance, as shown in FIG. 4F, the top portion of the rotatable assembly's body 332 is coplanar with the top surface 112 of the tray table 104. In this manner, the rotatable assembly 308 does not obstruct or hinder use of the tray table 104 when in the closed position. A passenger is therefore free to place items on the top surface 112 of the tray table 104 as desired. For example, the passenger may place food service items such as plates, cups, and utensils on the top surface 112. As shown in FIG. 4F, an optional cup holding inset 416 is provided to receive cups or the like. The lip 420 extends upward at the back end 120 of the tray table 104 to prevent items from falling off the back end of the tray table.

When use of a portable electronic device 204 is desired, the rotatable assembly 308 may be rotated to expose a cavity 132. As can be seen, the body 332 of the rotatable assembly 308 may be rotated such that the cavity 132 moves in an arc starting at the back end 120 of the tray table. FIG. 4G illustrates the body 332 having been moved from the closed position of FIG. 4F. As the rotation of the body 332 continues, the cavity 132 moves upward thereby positioning the cavity to

11

receive a portable electronic device **204**, such as shown in FIG. 4H-4I. In this open position, the cavity **132** holds the portable electronic device upright for use. FIGS. 4H-4I respectively provide a back and front perspective view of the tray table **104** with its rotatable assembly **308** in an open position and holding a portable electronic device **204**.

In one or more embodiments, the rotatable assembly **308** may be configured such that the opening of the cavity **132** is positioned above the top surface **112** of the tray table **104** when the rotatable assembly is in an open position, such as shown in FIGS. 4H-4I. This is advantageous in that the higher elevation helps prevent any dirt and debris that may be on the top surface **112** of the tray table **104** from entering the cavity **132**.

FIGS. 4J-4K illustrate side cross sectional views of the rotatable assembly **308** of FIGS. 4F-4I in operation. FIG. 4J shows the rotatable assembly **308** in a closed position while FIG. 4K shows the rotatable assembly in an open position. As can be seen, the cavity **132** is oriented toward the back end **120** of the tray table **104** in the closed position, while the cavity **132** is oriented upward to receive a portable electronic device **204** in the open position.

As described above, the cavity **132** may comprise a front wall **140**, a back wall **144** and one or more sidewalls **148**. The bottom **152** of the cavity **132** engages an edge or end of a portable electronic device to support the portable electronic device. An optional opening **156** at the bottom of the cavity **132** allows dirt and debris to exit the cavity, as described above. As can be seen from FIG. 4K for example, in the open position, dirt or debris that enters the cavity **132** would fall into the opening **156** and out of the body **332**. It is noted that dirt and debris that is too large to fit into the opening **156** would fall out of the cavity **132** when the tray table **104** is put in a stowed position, as described above.

The body **332** of the rotatable assembly **308** may be mounted to the tray table **104** via one or more rotatable mounts. FIG. 4L illustrates a back cross sectional view of the rotatable assembly **308** where the body **332** of the rotatable assembly is mounted to the body **136** of the tray table **104** via a pair of axels **336**. As can be seen, the axels **336** may extend from the left and right or lateral ends **424** of the body **332** and into a portion of the tray table's body **136** (or vice versa). The body **332** can thus rotate about the axels **336** between the closed and open positions, as shown respectively in FIGS. 4J-4K.

It is contemplated that some embodiments of the tray table **104** may comprise movable or removable portions to allow for cleaning and maintenance. Referring to FIGS. 5A-5C for example, a first portion **504** of the tray table **104** may be configured to separate from a second portion **508** of the tray table. at one or more separations **516**. In one or more embodiments, the two portions **504**, **508** may meet at or near the support **108**. In this manner, the two portions **504**, **508** would be separable at or near the support, such as delineated by Line 2 of FIG. 5 shown. Once separated, access to an interior portion of the support **108** is more easily achieved, such as to clean or maintain the support **108** or any elements associated with the support (such as adjustable elements).

One or more fasteners **512** may be used to allow the first portion **504** and second portion **508** to removably attach to one another. For example, as shown, the tray table **104** may comprise one or more hinges that allow the first and second portions **504**, **508** to fold relative to one another, thereby providing access to an interior portion of the support **108**. It is contemplated that the hinge may include a biasing mechanism and or locking mechanism to hold the first and second portions **504**, **508** in a planar configuration (such as shown in

12

FIG. 55A) during use. One or more additional fasteners **512** such as screws, pins, claps, magnets or the like may also or alternatively be used to hold the first and second portions **504**, **508** in the planer configuration.

Alternatively, the first and second portions **504**, **508** may be completely separable from one another, such as in the embodiments of FIGS. 5B-5C. For example, the first and second portions **504**, **508** may be configured to pull apart when detached from one another. In such embodiments, FIG. 5C illustrates the tray table **104** having its first and second portions **504**, **508** separated from one another.

It is noted that the first and second portions **504**, **508** may comprise mating surfaces or structures that secure the first and second portions together when connected. For example, the first and second portions **504**, **508** may have grooves, slots, tabs, or the like that correspond to one another. It is noted that, similar to Also, as stated above, one or more additional fasteners **512** may be used to secure the first and second portions **504**, **508** in a planar configuration. As shown in FIG. 5C for example, one or more pins **520** may connect and secure the first and second portions **504**, **508** together when assembled.

It is contemplated that, when mounted to an aircraft passenger seat, only the first or second portion **504**, **508** would be attached to the tray table support arms of the seat. This permits the first and second portions **504**, **508** to be removable from one another (such as to clean or maintain the support **108**) without removing the tray table **104** from the seat. Alternatively, both the first and second portions **504**, **508** may be attached to the tray table support arms, such as to secure the first and second portions together in a planar configuration. In such case, additional fasteners for holding the first and second portions together need not be used.

FIGS. 6A-6F illustrate various slots or cavities **132** having biasing mechanisms **604** that may be used to help hold or secure a portable electronic device **204**. In general, a biasing mechanism **604** applies force to a portable electronic device **204** to increase friction between the portable electronic device and a cavity **132** in which it has been inserted. For instance, a biasing mechanism **604** may clamp or squeeze a portion of a portable electronic device **204** to help secure the portable electronic device within a cavity **132**. As can be seen from FIG. 6A-6F, a biasing mechanism **604** may be used in embodiments with a fixed support **108** or rotating assembly **308**, including those disclosed above.

FIGS. 6A-6B provide a side cross sectional view of a first biasing mechanism **604** in operation. As can be seen, a biasing mechanism **604** may comprise a presser **620** that applies force to a portable electronic device **204** to help secure the portable electronic device. In the embodiment of FIGS. 6A-6B, the presser **620** is pivotally attached to the body **132** of a tray table **104** at a mount **624** within a cavity at back end **120** of the tray table via a connecting rod **616**. It is noted that a pivot or rotating mount may attach the connecting rod **616** at either or both of its ends. The presser **620** is biased or pushed into a cavity **132** of the tray table **104** by one or more biasing devices **612**. This causes the presser **620** to protrude into the cavity **132**.

A presser **620** may also be coupled to one or more biasing devices **612**, such as various springs, elastic or other resilient device/material. A variety of biasing devices **612** are illustrated in FIGS. 6A-6B. It is contemplated that only a single biasing device **612** is needed in most embodiments however. It can be seen with reference to FIGS. 6A-6B that a biasing device may bias movement of a presser **620** at its pivot (e.g., at a rotating mount **624**), at its connecting rod **616**, or at the presser **620** itself

13

In FIGS. 6A-6B, the biasing device **612** directly connected to the presser **620** expands to push the presser into the cavity **132**, the biasing device connected to the connecting rod **616** compresses to pull the presser into the cavity, and the biasing device at the rotating mount **624** applies a rotational force with rotates the presser into the cavity. It is noted again that only a single biasing device **620** need be used in most embodiments. The presser **620** may protrude into the cavity **132** through an opening **608** in the back wall **144** (or front wall **140**).

As can be seen from FIG. 6B, when a portable electronic device **204** is inserted in the cavity **132**, the presser **620** is forced at least partially out of the cavity **132** to allow the cavity to accommodate the portable electronic device. In this position, the presser **620** continues to exert pressure or force on the portable electronic device **204** from its one or more biasing devices **612**.

FIGS. 6C-6D provide a cross sectional view of a second biasing mechanism **604**. As can be seen, the presser **620** in this embodiment is within the cavity **132** at a first wall **144** of the cavity. A biasing mechanism **612** applies force to push the presser **620** towards the opposite wall **140** of the cavity. Alternatively or in addition, a biasing mechanism **612** may be at a pivot point of the presser **620** and apply rotational force at such point to push the presser **620** towards the opposite wall. The presser **620** is pivotally or movably mounted to a mount **624**, similar to above. It is noted that a presser **620** may move linearly rather than rotationally in some embodiments. For example, a presser **620** may extend and retract parallel to a front or back wall **140**, **144**.

As can be seen in FIG. 6D, when a portable electronic device **204** is inserted in the cavity **132**, the presser **620** is forced back towards the first wall **144** to allow the cavity to accommodate the portable electronic device. In this position, the presser **620** continues to exert pressure or force on the portable electronic device **204** from its one or more biasing devices **612**.

A presser **620** may be rounded, angled or both to prevent a presser **620** from obstructing entry of a portable electronic device **204** into a cavity **132**. As can be seen in FIGS. 6A-6B for instance, the presser **620** is rounded and may rotate at the distal end of its connecting rod **616** to allow insertion of a portable electronic device **204** without obstruction. In the embodiment of FIGS. 6C-6D, the presser **620** has an angled distal end so as to also allow a portable electronic device **204** to be inserted into its cavity **132** without obstruction.

FIGS. 6E-6F illustrate another embodiment of a biasing mechanism **604** where the presser **620** forms one of the walls **140** of the cavity **132**. FIGS. 6E-6F also show that a biasing mechanism **604** may be used in embodiments having a rotating assembly **308**.

As can be seen, the presser **620** in this embodiment is pivotally or movably mounted via a mount **624**. A biasing device **612**, such as a spring, is at the mount **624** and provides a rotational bias which forces or moves the presser **620** towards the opposite wall **144** of the cavity. In one or more embodiments, the biasing device **612** may be about or at a pivot or axel of a mount **624** to apply rotational force to the presser **620**.

As can be seen from FIG. 6F, the bias of the presser **620** is overcome as a portable electronic device **204** is inserted into the cavity **132**. The presser **620** is moved outward to accommodate the portable electronic device **204** and continues to apply inward pressure or force to help secure the portable electronic device in the cavity **132**.

Though shown at or forming a front wall **140** or back wall **144** of a cavity **132** in FIGS. 6A-6F, it is contemplated that a

14

biasing mechanism **604** may be at either or both walls **140**, **144** of a cavity. In addition, it is contemplated that a presser **620** need not be pivotally or rotatably mounted in all embodiments. For example, a presser **620** may be mounted to a telescoping mount that moves in a linear inward and outward fashion. A biasing device **612** can be used to bias the telescoping mount outward to apply force or pressure to a portable electronic device **204** when inserted.

FIGS. 6G-6K illustrate another exemplary embodiment comprising a rotatable assembly **308** and a presser **620**. The perspective view of FIG. 6G illustrates the rotatable assembly **308** installed in an exemplary tray table **104** and rotated to an open position. A portable electronic device **204** is received within the cavity **132** of the rotatable assembly **308** and held for use by a passenger or other user. A body **332** of the rotatable assembly **308** may be rotatably mounted to a tray table **104** via one or more axels **336** (and openings **632** for receiving such axels), pivots or other rotatable mounts. Similar to above, the presser **620** is movable to receive and hold a portable electronic device with a cavity **132** of the rotatable assembly **308**.

FIGS. 6H-6I respectively illustrate top and bottom perspective views of an exemplary presser **620** in a retracted position, while FIGS. 6J-6K respectively illustrate top and bottom perspective views of the presser in an extended position. As can be seen, the presser **620** may form or comprise a front wall **140** and bottom **152** of a cavity **132** and be movable (i.e., extendable and retractable) therewith. A body **332** of a rotating assembly **308** may comprise a notch **636** to receive a presser **620**. It can be seen from FIGS. 6H and 6J for example, that the body **332** comprises a central notch **636** where the presser **620** is movably mounted.

In a retracted position the front wall **140** and back wall **144** are closer to one another as compared to an extended position. This allows a cavity **132** to accommodate portable electronic devices of various widths. Also, a biasing mechanism **604** may apply a force to move the presser **620** (and therefore the front wall **140**) toward the back wall **144**. This too helps secure a portable electronic device within a cavity **132**.

As can be seen from FIG. 6K, one or more biasing devices **612** may be used to produce such force. In the embodiment of FIG. 6K for example, biasing devices **612** comprising springs extend between the body **332** of the rotatable assembly **308** and the presser **620**. The biasing devices **612** apply force causing the presser **620** to be biased to a retracted position, such as that shown in FIG. 6I.

It is noted that a biasing mechanism **604** may include one or more guides **628** to guide or control the movement if a presser **620**. As shown in FIG. 6K for example, one or more guide pins **628** extend from the body **332** and into corresponding openings of the presser **620** to guide the movement of the presser as it moves between an extended and retracted position. A pin **628** may have an enlarged distal end to prevent the presser **620** from extending beyond a predefined point. It is contemplated that one or more guides **628**, may be at the lateral ends of a presser **620** in some embodiments. For example, a linear channel may be formed in each lateral end of a presser **620** while corresponding rails extend from the sides of the notch **636** of a body **332**, or vice versa.

In some embodiments, a biasing mechanism **604** need not be provided. In such embodiments, a presser **620** may be held in position by friction, such as between one or more pins **628** and their corresponding openings. Alternatively, one or more detents and corresponding tabs may be used to hold a presser **620** in position. For example, a detent or tab may be formed at the lateral ends of a presser **620** with a corresponding tab or detent at a body **332** of a rotatable assembly **308**.

15

FIGS. 7A-7B illustrate a side view of an exemplary tray table **104** having a collapsible slot or cavity **132**. As can be seen, a slidable or movable bracket **704** forms a back wall **144** and bottom **152** of the cavity, while a front wall **140** of the cavity **132** is formed by the tray table's body **136**. The bracket **704** is slidable at a back end **120** of the tray table **104** to allow a cavity **132** to be expanded and collapsed.

For instance, the bracket **704** has been moved toward the tray table's body **136** in FIG. 7A. This collapses the cavity **132**. In FIG. 7B, the bracket **704** has been moved outward from the body **136** to expand the cavity **132**. Once expanded, a cavity **132** can receive, support and secure a portable electronic device therein, such as described above. It is noted that one or more biasing devices **612**, such as springs, may pull the bracket **704** toward the body. This bias applies pressure or force to a portable electronic device to help secure the portable electronic device once inserted in the cavity **132**. Alternatively or in addition, it is noted that the back wall **144** may be formed by a presser **620**, such as described above with regard to FIGS. 6E-6F. In another embodiment, a presser **620**, such as described with regard to FIGS. 6A-6D, may be at the front wall **140** or back wall **144** of the cavity.

Typically, a bracket **704** will comprise a base **716** and an upright **712**. The base **716** and upright **712** may be perpendicular to one another such as shown in FIGS. 7A-7B. Alternatively, the base **716** and upright **712** may extend at various angles. For example, an upright **712** may be angled backwards to allow a portable electronic device to be supported at a reclined angle. It is noted that, in some embodiments, a portion of a tray table's body **136** may have a notch **708** or removed to accommodate the base **716** of a bracket **704**. Alternatively a body **136** may have a slot or cavity therein to receive the base **716** of a bracket **704**.

It is noted that a notch **708** need not be provided in every embodiment. For instance, in a retrofit where the bracket **704** is installed on a preexisting tray table **104** the bracket may be movably secured at a bottom surface of such tray table. Alternatively, a notch **708** may be machined or otherwise formed in the preexisting tray table **104**.

One or more slides may be used to secure a bracket **704** to a tray table's body **136**. A slide may comprise a rail, groove, or other structure that allows a bracket **704** to move inward and outward to respectively collapse and expand a cavity **132**. In FIGS. 7A-7D, slides comprising a peg **720** and rail **724** movably attach the bracket **704** to the tray table's body **136**. As can be seen, the pegs **720** have an enlarged head at their distal ends. One or more narrower pins extend from the enlarged head and are secured to the body **136**. As shown in the bottom views of FIGS. 7C-7D, the one or more pins slide within rails **724** of the base **716** of a bracket **704**, while the enlarged heads secure base **716**.

In FIG. 7C, the cavity **132** is collapsed. The bracket **704** can then be slid outward to expand the cavity, such as shown in FIG. 7D. In an expanded position, the front wall **140** and back wall **144** are sufficiently separated to accept a portable electronic device. Thereafter, a portable electronic device can be inserted into the cavity. When no longer desired, the cavity **132** can again be collapsed by moving the bracket inward towards the tray table's body **136**. This reduces the size of the tray table **104** allowing it to be stowed in a more space saving manner.

16

While various embodiments of the invention have been described, it will be apparent to those of ordinary skill in the art that many more embodiments and implementations are possible that are within the scope of this invention. In addition, the various features, elements, and embodiments described herein may be claimed or combined in any combination or arrangement.

What is claimed is:

1. A tray table for holding a portable electronic device in a vehicle comprising:

a body having a top surface;

a slot in the body, the slot comprising a first wall and a second wall, wherein the slot is dimensioned to receive an edge of a planar portable electronic device and to hold the planar portable electronic device upright when the planar portable electronic device is received within the slot;

a biasing device connected to the second wall that forces the second wall towards the first wall; and one or more mounts for attaching the tray table to a portion of the vehicle.

2. The tray table of claim 1 further comprising an opening at a bottom of the slot.

3. The tray table of claim 1, wherein the first wall is taller than the second wall.

4. The tray table of claim 1 further comprising a rotatable assembly, the rotatable assembly comprising:

a recess in the body;

a rotatable body, wherein the slot is formed in the rotatable body; and

one or more rotatable mounts securing the rotatable body to the body within the recess.

5. A tray table for holding a portable electronic device in a vehicle comprising:

a body having a top surface and a back end;

one or more mounts for attaching the tray table to a portion of the vehicle;

a bracket comprising a base and an upright at a back end of the tray table;

one or more slides attached to the body, wherein the bracket is secured to the body by the one or more slides and movable between a retracted position and an extended position along the one or more slides; and

a collapsible slot comprising a bottom formed by the base of the bracket, a front wall formed by the back end of the body, and a back wall formed by the upright of the bracket;

wherein the collapsible slot is arranged to receive an edge of the portable electronic device and hold the portable electronic device upright when the bracket is in its extended position.

6. The tray table of claim 5 further comprising a biasing device connected to the bracket that pulls the bracket towards the body.

7. The tray table of claim 5 further comprising an opening in the bottom of the collapsible slot.

8. The tray table of claim 5, wherein the one or more slides each comprise one or more pegs and a rail.
